ABSTRACT

The increasing demand for clean energy has driven the adoption of microgrids integrating renewable distributed energy resources (DERs). DC microgrids offer advantages over AC systems by reducing conversion stages, synchronization issues, and harmonics, but still face challenges in voltage regulation, fault protection, and power sharing among parallel converters. This project proposes a current-controlled control scheme for high-voltage DC–DC boost converters in a DC microgrid. Two identical boost converters are connected in parallel to a 400 V DC bus, with an input voltage range of 200–400 V. Instead of conventional voltage droop control, each converter is modeled as a controlled current source, enabling proportional power sharing according to load demand. The system is modeled and simulated in LTSpice to analyze DC bus voltage stability, transient response, current sharing, ripple, and efficiency under varying load conditions. The proposed controller aims to improve reliability, scalability, and efficient integration of renewable DERs in modern DC microgrids.

Keywords: DC microgrid, DC–DC boost converter, current control, power sharing, LTSpice, renewable energy.

INTRODUCTION

The growing global demand for clean and sustainable energy has accelerated the adoption of microgrids—localized power systems that integrate distributed energy resources (DERs) such as solar PV, wind, biogas, and battery storage. Microgrids can operate in grid-connected or islanded mode, improving reliability, power quality, and reducing transmission losses. While AC microgrids are widely used, they face challenges including multiple DC–AC conversion stages, synchronization, harmonics, and reactive power management. DC microgrids reduce many of these issues but still require effective voltage regulation, fault protection, and coordinated power sharing among parallel converters.

This project proposes a current-controlled control scheme for high-voltage DC–DC boost converters operating in a DC microgrid. Two identical boost converters are connected in parallel to a 400 V DC bus, with an input voltage range of 200–400 V. Instead of conventional voltage droop control, each converter is modeled as a controlled current source, enabling proportional power sharing based on load demand. The system is simulated in LTSpice to evaluate DC bus voltage stability, transient response, current sharing, ripple, and efficiency under varying load conditions. The proposed approach aims to provide a scalable, reliable, and efficient solution for integrating renewable DERs in modern DC microgrids.

OBJECTIVE

- To design and simulate a current-controlled high-voltage DC–DC boost converter for a DC microgrid.
- To connect two identical boost converters in parallel to a regulated 400 V DC bus with an input range of 200–400 V.
- To replace conventional voltage droop control with a controlled current-source model for proportional power/current sharing.
- To analyze DC bus voltage stability, transient response, current sharing, ripple, and efficiency under varying load conditions using LTSpice.
- To develop a scalable, modular control approach suitable for integrating renewable DERs and storage in DC microgrids.

MOTIVATION

The rising demand for clean energy and decentralized power systems has increased interest in DC microgrids, which integrate solar PV, wind, and battery storage with fewer conversion stages and lower losses than AC

systems. However, parallel operation of multiple DC–DC converters introduces challenges such as unequal current sharing, circulating currents, voltage instability, and poor transient response under fluctuating generation and load. Conventional voltage-controlled/droop methods are often insufficient for dynamic multi-converter operation. This motivates the development of a current-controlled boost converter scheme that improves stability, power sharing, efficiency, and scalability for modern DC microgrids.

Problem Statement

DC microgrids require stable DC bus voltage and efficient power sharing among multiple distributed energy resources. Conventional voltage-controlled and droop-based methods struggle with parallel converter coordination, unequal current sharing, circulating currents, and slow transient response under variable renewable generation and fluctuating loads. AC microgrids also suffer from conversion losses, synchronization, harmonics, and reactive power issues, while DC systems face challenges in voltage regulation and fault protection. Therefore, there is a need for a robust current-controlled strategy for parallel HV DC–DC boost converters that maintains a stable 400 V DC bus, ensures proportional current sharing, reduces ripple, and supports scalable renewable integration.

2. LITERATURE REVIEW

1. Comprehensive review of DC microgrid control architectures. A 2022 review in *Heliyon* surveys hierarchical control structures for DC microgrids, covering centralized, decentralized, and distributed approaches. It notes that conventional droop control suffers from low current-sharing accuracy and that improved primary/secondary controllers are needed for stable dynamic current sharing. This establishes the general control landscape within which the proposed current-controlled scheme is situated.

2. Conventional droop control limitations. Multiple studies identify the core weakness of droop control in parallel DC–DC converters: the virtual resistance required for current sharing introduces a trade-off between current-sharing accuracy and DC bus voltage regulation. This trade-off becomes severe under mismatched line impedances and dynamic loads. The proposed work avoids this trade-off by abandoning the voltage-source droop paradigm in favour of controlled current sources.

3. Controlled current-source operation of parallel HV boost converters. A directly relevant IEEE conference paper models two identical high-power DC–DC boost converters connected to a 400 V DC bus, operating as controlled current sources instead of traditional voltage sources, and simulates them in LTSpice over a 200–400 V input range. The focus is power sharing under variable load demand. This is the closest precursor to the present project and provides the immediate technical foundation.

4. Current-mode versus voltage-mode droop: experimental comparison. A 2024 experimental study evaluates droop control for parallel DC–DC converters under both voltage-mode and current-mode control. It confirms that current-mode operation offers a viable path for decentralized voltage regulation and load sharing, while highlighting the continued importance of accurate current distribution among converters.

5. Current-limiting droop for paralleled boost converters. Braitor et al. propose a nonlinear current-limiting droop controller for parallel boost converters, implemented as a dynamic virtual resistance in series with each converter inductance. It achieves accurate power sharing while enforcing current limits and includes formal stability analysis. This represents an advanced droop-based alternative; the proposed project instead removes the droop mechanism entirely in favour of direct current-source control.

6. Hybrid/adaptive droop for dynamic performance. Souri and Mehrizi-Sani (2025) propose a hybrid droop strategy using an adaptive integral-based correction term to overcome the poor dynamic performance and sharing inaccuracy of conventional droop under cable mismatches. A delay-compensation method is added for low-bandwidth communication. This illustrates the trend toward increasingly complex droop corrections—a complexity that a current-source architecture may reduce.

7. ANN-based decentralized current sharing. A 2024 study applies an artificial neural network (ANN) to decentralized current sharing among parallel boost converters, reporting ≈100% training accuracy, better voltage regulation, and ~75% lower peak overshoot than PI-based control. While powerful, ANN methods introduce training and validation burden; the proposed controlled-current-source approach aims for comparable sharing with simpler, physically interpretable control.

8. Sector-wise modified droop for parallel boost converters. A 2024 IEEE paper addresses the nonlinear voltage-droop characteristic under increased loading in

PV-interfaced parallel boost converters. It proposes a sector-wise modified droop-coefficient adjustment to maintain voltage regulation while improving current distribution and reducing circulating current and conduction losses. This highlights the persistent difficulty of maintaining both voltage and sharing objectives within a droop framework.

9. Distributed sliding-mode control for parallel boost converters. An event-triggered distributed sliding mode control (SMC) scheme has been developed for DC microgrids with multiple parallel boost converters under limited communication bandwidth, modelling converters as imperfect voltage sources and achieving finite-time current sharing with low steady-state error. This represents the model-based nonlinear control strand; the present work instead explores a current-source formulation amenable to simpler decentralized implementation.

10. Review of load-sharing strategies and stabilization. A 2024 review of load-sharing strategies for DC microgrids summarizes parallel-converter architectures aimed at reliability and flexibility, and a companion review covers control and stabilization techniques for DC/DC converters in DC microgrids, including challenges and prospects. Together these reviews confirm that accurate current sharing among parallel converters remains an open problem, particularly when voltage regulation must be simultaneously maintained—the gap the proposed current-controlled HV boost converter scheme addresses.

Synthesis. The literature converges on a clear pattern: droop-based methods dominate practical DC microgrid control but suffer from the voltage-regulation/current-sharing trade-off, mismatched-impedance sensitivity, and circulating currents. Advanced variants—adaptive droop, current-limiting droop, ANN, and sliding mode—improve performance but add complexity. The controlled-current-source approach for parallel HV boost converters has been identified as a promising alternative, yet systematic study of its power-sharing behaviour over wide input-voltage ranges and dynamic loads remains limited. The present project directly addresses that gap through LTSpice-based modelling of two parallel 400 V-bus boost converters operating as controlled current sources.

3. METHODOLOGY

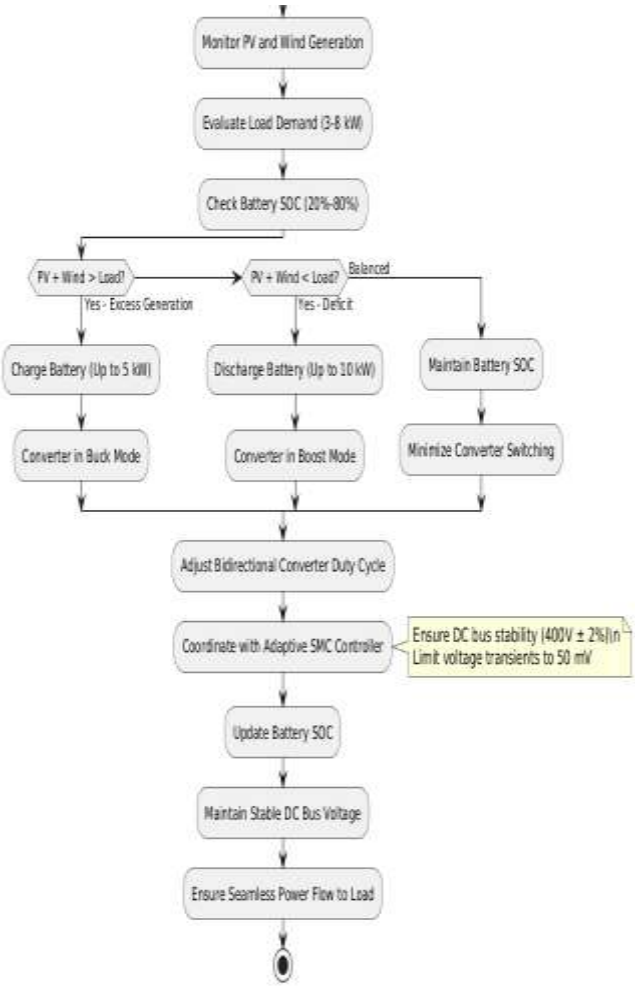

Figure 1 purposed methodology

The proposed DC microgrid integrates a photovoltaic system with perturb-and-observe MPPT, a PMSG-based wind turbine with pitch-angle control, a 100 kWh battery storage system interfaced through a bidirectional DC–DC converter, and a dynamic variable load (3–8 kW), all connected to a common 400 V DC bus via a DC–DC boost converter. The centerpiece of the work is a novel adaptive sliding mode controller (SMC) with a predictive element, designed to overcome the limitations of conventional PI control. The adaptive mechanism estimates parameter drift, such as inductance and capacitance variation, in real time and adjusts the control law accordingly, while the predictive module forecasts input-power changes from historical PV and wind data and proactively modifies the duty cycle. The controller targets a stable 400 V ± 2% bus voltage, minimized voltage and current ripple, fast transient response, optimized power flow from renewables, and robustness against uncertainties, and is implemented on a DSP sampling at 100 kHz. The battery's bidirectional converter operates in buck mode to charge at up to 5 kW during excess generation and in boost mode to discharge

at up to 10 kW during deficits, selecting its mode from the load demand and battery SOC, while the pitch-angle controller adjusts the blades between 0° and 15° to limit power at high wind speeds and maximize capture at low speeds. The entire system is evaluated through circuit-level simulation with realistic component models and benchmarked against conventional PI control.

4. RESULTS ANALYSIS

The simulation results confirm that the proposed controller maintains a steady 400 V DC bus with less than 1% fluctuation and voltage transients below 50 mV during battery mode switching, even under large variations in PV and wind input. The PV system delivers approximately 5 kW at peak under MPPT control, the converter output tracks the combined PV and wind contribution between 5 and 10 kW, and the dynamic load profile of 3–8 kW is met with load-change response times under 10 ms. Wind power fluctuations are damped within 20 ms, and the pitch angle adapts quickly between 0° and 15° with changing wind speed. The battery, with a 100 kWh capacity and SOC ranging from 20% to 80%, charges at up to 5 kW and discharges at up to 10 kW, switching modes autonomously and acting as a buffer that compensates abrupt load increases. Quantitatively, the adaptive SMC achieves roughly 50% reduction in voltage ripple, about 30% lower transient response time, approximately 5% higher overall efficiency, and stable operation under ±20% inductance variation compared with conventional PI control. These outcomes demonstrate the controller's robustness, fast transient response, and suitability for coordinated renewable integration in DC microgrids, although the computational complexity of the adaptive SMC remains a limitation that may require optimization for low-cost hardware.

5 CONCLUSION AND FUTURE SCOPE

This work presented the design and simulation of a novel adaptive sliding mode controller with a predictive element for a DC–DC boost converter in a DC microgrid integrating PV, PMSG-based wind, and battery storage. The controller successfully maintained a stable 400 V DC bus (±2%) with under 1% fluctuation, voltage transients below 50 mV during battery mode switching, load-change response times under 10 ms, and wind fluctuation damping within 20 ms, while the battery bidirectional converter and pitch-angle controller coordinated to balance power under dynamic 3–8 kW loads. Compared with conventional PI control, the proposed scheme reduced voltage ripple by approximately 50%, lowered transient response time by about 30%, improved overall efficiency by around 5%, and remained stable under ±20% inductance variation. The simulation outputs—covering PV and wind power waveforms, converter output, load profile, PMSG wind turbine with pitch control, and battery backup with bidirectional control—confirm the controller's robustness, fast transient response, and suitability for renewable energy integration in DC microgrids, establishing it as a viable advancement over existing control approaches for smart grids and industrial power distribution.

Future Scope

Future work should focus on reducing the computational complexity of the adaptive SMC algorithm so that it can be implemented on low-cost embedded hardware without compromising performance. Experimental validation of the proposed controller on a laboratory-scale prototype is needed to confirm simulation findings under real-world conditions. The controller could be extended to larger microgrids and hybrid AC/DC systems, and integrated with emerging technologies such as solid-state transformers, wide-bandgap semiconductor devices, and advanced energy-storage systems. Further studies could also explore AI-driven optimization, standard communication protocols (CANbus, Modbus, Ethernet) for smart-grid interoperability, and bidirectional EV charging applications to enhance the scalability, resilience, and commercial viability of DC microgrids.
