Abstract—Nowadaysa very famous epidemic of COVID-19 is going on. The epidemic is most prevalent where humans are overcrowded and come in contact with each other so all people are worried about current situation. Like some people go outside to come to home they are worried about coronavirus virus and second thing is humans are not aware about COVID-19 medicine so, in our Modern human care services application we propose to develop an application which can predict the vulnerability of a COVID-19 given basic symptoms like fever, cough, diarrhea etc. and we also give COVID-19 related medicine information to take during corona risk. The ensemble learning approach is one of the most reliable techniques for predicting results.

Key Words: classification algorithms, regression algorithms, covid-19, prediction

I. INTRODUCTION
In December 2019, the novel coronavirus appeared in the Wuhan city of China [1] and was reported to the World Health Organization (W.H.O) on 31st December 2019. The virus created a global threat and was named as COVID-19 by W.H.O on 11th February 2020 [1]. The COVID-19 is the family of viruses including SARS, ARDS. W.H.O. declared this outbreak as a public health emergency [1] and mentioned the following; the virus is being transmitted via the respiratory tract when a healthy person comes in contact with the infected person. The virus may transmit between persons through other roots which are currently unclear. The on the incubation period of the middle east respiratory syndrome (MERS), and the severe acute respiratory syndrome (SARS). According to W.H.O the signs and symptoms of mild to moderate cases are dry cough, fatigue and fever while as in severe cases dyspnea (shortness of breath), Fever and tiredness may occur. The persons having other diseases like asthma, diabetes, and heart disease are more vulnerable to the virus and may become severely ill. The person is diagnoses based on symptoms and his travel history. Vital signs are being observed keenly of the client having symptoms. No specific treatment has been discovered as on 10th April 2020, and patients are being treated symptomatically. The drugs like hydroxychloriquine, antipyretic, anti-virals are used for the symptomatic treatment. Currently, no such we may take some precautions to prevent this disease. By washing hands regularly with soap for 20 s and avoiding close contact with others by keeping the distance of about 1m may reduce the chances of getting affected by this virus. While sneezing, covering the mouth and nose with the help of disposable tissue and avoiding the contact with the nose, ear and mouth can help in its prevention. Till 10th of April 2020, almost 1.6 million confirmed cases of coronavirus are detected around the globe. Almost 97 K persons have died and 364 K persons have recovered from this deadly virus[1]. Since no drug or vaccine is made for curing the COVID-19. Various paramedical companies have claimed of developing a vaccine for this virus. Less testing has also given rise to this disease as we lack the medical resources due to pandemic. Since thousands and thousands are being tested positive day by day around the globe, it is not possible to test all the persons who show symptoms.

Motivated by the event of many machine learning ways for the prediction of covid-19 condition risk, and we have a tendency to propose a sort of homogeneous ensemble learning methodology. The proposed methodology involves the employment of a mean based approach to randomly partition the dataset into smaller subsets and applying the classification and regression algorithmic program to model every partition.

II. RELATED WORK
This section discusses some learning strategies. ASA allows all users to auto-diagnose in their clinical conditions and to determine their levels of risk pattern by fulfilling the type of self-assessment score (SAS) is given in the app, ASA. ASA helps people to decide whether they are at risk of coronavirus infection (COVID-19) or the flu without rushing to their 3]. The patient is at a higher level of risk (HLOR) or being diagnosed with COVID-19 and must seek medical support or obey the Union Health Ministry's self-isolation advice or not guided by ASA. The consumer is not unwell and shows no symptoms of COVID-19 then it will show the 0 (negative) is the outcome of the self-assessment test (SAT) which is indicating that his pattern of the risk (POTR) for COVID-19.

Machine learning and natural language processing use big data for pattern recognition, explanation, and prediction. Classification is one of the major task in text mining and can be performed using different algorithms[1]. Once the COVID-19 is detected in a person, the question is whether and how intensively that person will be affected. Not all COVID-19 positive patients will need rigorous treatment. Currently, no specific treatment has been discovered as on 10th April 2020, and patients are being treated symptomatically.

medical resource allocation and utilization. [1] used machine static prediction algorithm to predict the mortality risk of a learning to develop a prognost used machine learning to develop a prognosperson that has been infected.

3.2 Logistic regression

Logistic regression is a statistical and machine learning technique that can classify data sets in a data set based on the values of input fields. Predict the dependent variable based on one or more sets of explanatory variables to predict the outcome. It can be used for both binary classifications and multi-class classification. Logistic regression is one of the machine learning algorithms, which is relatively widely used in research to assess the risk of complex diseases. Therefore, the purpose of this study is to determine the most important predictors of cardiovascular disease and use logistic regression analysis to predict the overall risk. [20]

3.2.2 Support vector machine(SVM)

Support vector machine (SVM) is a supervised machine learning algorithm for classifying text into different categories [1]. It takes \( n \) number of features for the particular text with the given label. Here we have taken 20 features that are of nature unigram and bigram as the dataset is small. Here the data points of the training set \( n \), where \( n \) is the number of features taken. The 20 features that have been selected in feature engineering with values are represented in the form of a table and are supplied as an input.

3.2.3 Decisiontrees

An alternative approach for classification it partitions the input space into regions and classifies every region independently [7]. The 20 features that have been selected in feature engineering with values are represented in the form of a table and are supplied as an input. It splits the space recursively according to the inputs and classifies at the bottom of the tree. The leaf nodes classify the text into four classes. While building a decision tree, a vital function needs to be considered which is known as the splitting criterion. The function defines how data should be split in order to maximize performance.

IV. DATASET AND PERFORMANCE METRICS

In this paper, one covid-19 dataset is used, the symptoms based dataset obtained from the Kaggle website [10]. The previous contains 303 instances and 20 attributes, whereas the latter consists of 5000 instances and 20 attributes. The Symptoms based dataset contains missing attributes, and it’s preprocessed to form it appropriate for machine learning. This dataset health records like heart disease, fever, dry cough, running nose, diabetes, etc. For our experiments, the 75-25 train- test holdout validation scheme is used; this is often to enable us to form a good and higher comparison between our proposed technique and former studies that used an analogous dataset. To adequately assess the performance of the proposed methodology, numerous performance indices are used, including accuracy, precision, sensitivity, specificity and F1 score. The accuracy is the proportion of the total number of predictions that were correct, and precision is the magnitude relation of correct positive predictions to the number of positive results predicted. At the similar time, Sensitivity (True Positive
rate) measures the proportion of positives that are correctly identified, while Specificity (True Negative rate) measures the proportion of negatives that are correctly identified and F-score is the harmonic mean between precision and sensitivity. The mathematical representations of these performance metrics are:

\[
\text{Accuracy} = \frac{TP+TN}{TP+FP+FN+TN} \quad (1)
\]

\[
\text{Precision} = \frac{TP}{TP+FP} \quad (2)
\]

\[
\text{Sensitivity} = \frac{TP}{TP+FN} \quad (3)
\]

\[
\text{Specificity} = \frac{TN}{TN+FP} \quad (4)
\]

\[
\text{F1 Score} = \frac{2 \times (\text{Sensitivity} \times \text{Precision})}{\text{Sensitivity} + \text{Precision}} = \frac{2 \times TP}{2 \times TP + FP + FN} \quad (5)
\]

Where, TP represents the number of true positives, TN represents the number of true negatives, FP represents the number of false positives and FN represents the number of false negatives.

V. RESULTS AND DISCUSSION

To validate the effectiveness of the proposed method, a comparative study is conducted with other well-known machine learning methods. The methods include k-nearest neighbor (KNN), Logistic regression (LR), support vector machine (SVM), classification and regression tree (CART), gradient boosting (GB), and random forest (RF).

1. Registration and Login

We build one android application for the detection of covid-19. User can use the app by login to the application and registration page is also provided. After that user can check self-assessment application will predict that user have a covid-19 or not. And user also view the medicine and covid-19 hospital list in to the application.
2. **Self-Assessment**

3. **View medicine**

1. **HospitalList**
2. Do & Don’ts

Do's and Don'ts to Stay Safe

CONCLUSION

The Modern Human Care System using Machine learning Algorithm. COVID-19 has shocked the world due to its non-availability of vaccine or drug. Various researchers are working for conquering this deadly virus. The proposed ensemble achieved accuracy of 96% on Symptoms based test sets using Heroku cloud services. More feature engineering is needed for better results and deep learning approach can be used in future.

ACKNOWLEDGMENT

We thank Mr. Ankit D. Prajapati for his assistance with paper and for helping out as our mentor/guide throughout the process.
