

A Comparative Study of Time and Cost Optimization in Project

Management: Primavera P6 & Linear Programming with Lingo Solver

Abstract - In an effort to boost efficiency and reduce costs, computer-based solutions have become more popular for project management. Although Primavera P6 and other traditional tools have proved essential for project planning and control, difficulties still arise with complicated projects. An innovative approach is provided by the development of mathematical optimization techniques, especially Linear Programming (LP) with programmes like Lingo Solver. The purpose of this study is to compare the time and cost optimization of Primavera P6 and Lingo Solver's LP. The goals are to analyse the advantages and disadvantages, evaluate the effectiveness and adaptability, and offer useful information to decision-makers.

Application of Lingo Solver's LP is found to significantly reduce project duration, with a significant impact on cost trends. On the other hand, Primavera P6 shows that project duration can be reduced while maintaining the same level of cost. The study highlights how the duration of the project, additional indirect expenses, and costs interplay dynamically throughout the duration of the project. This research provides useful insights to the continuing discussion on project management methodologies by bridging the gap between conventional project management tools and advanced optimization techniques. This will help decision-makers overcome the complexities of project optimization for optimal results in practical applications.

Key Words: Optimization, Construction project, Linear programming, Primavera p6, Lingo, Project management, Mathematical model, Time-cost trade-off.

1. INTRODUCTION

1.1. BACKGROUND OF STUDY

Over the years, there has been a significant evolution in project management, with a focus on computer-based solutions to increase productivity, reduce costs, and ensure project execution. The utilisation of traditional project management software, such as Primavera P6, has been essential in simplifying project planning, scheduling, and control. This software provides functionalities including resource allocation, Gantt charts, and critical path analysis. However, problems with cost minimization and resource allocation continue to arise as projects become more complicated. Project management has taken on a new dimension with the introduction of mathematical optimization techniques, specifically Linear Programming (LP) with Lingo Solver. As a methodical approach to cost-effectiveness and resource optimization, linear programming is a mathematical optimization technique that looks for the most optimal solution using mathematical modelling.

The necessity to investigate and comprehend the benefits and drawbacks of both conventional and mathematical optimization approaches is what prompted this comparative study. Organisations must choose which tool to use depending on the demands of the project, available funds, and the difficulty of the work. This research aims to contribute to the ongoing discourse in project management by offering empirical insights into the cost optimization capabilities of Primavera P6 and Linear Programming with Lingo Solver.

1.2. EVOLUTION OF PROJECT MANAGEMENT SOFTWARE

Project management has evolved throughout the years from manual techniques to computer-based solutions. Project planning and execution now require the use of software tools like Primavera P6, which offers functions like Gantt charts, resource allocation, and critical path analysis. These tools are designed to facilitate decision-making, increase teamwork, and expedite the management process.

1.3. CHALLENGES FACED IN TRADITIONAL APPROACH

- 1. The accuracy needed for complex resource allocation and cost optimization may be lacking in traditional project management software.
- 2. As projects get more complicated, more complex project structures may be difficult for standard tools to manage and OPTIMIZE.
- 3. In project contexts that are changing quickly, it may be difficult for traditional methods to react in real time and modify resource allocations appropriately.

SJIF Rating: 8.176

ISSN: 2582-3930

4. Conventional approaches frequently depend on heuristics and general guidelines, which may result in less-than-ideal results in terms of cost and resource usage.

2. LITERATURE REVIEW

The literature review that follows includes some theoretical and analytical research that has been done in this field.

- [1] Patel (2019) researched on 'Optimization in construction management', It covers a range of topics related to optimization in the construction sector. In order to achieve the intended output or to maximize profit margins under specific input conditions, optimization entails choosing the optimal combination of inputs. The paper emphasizes the need for thorough planning and application of optimization strategies. The article suggests using digital platforms for communication, creating a proper hierarchy within project teams, resource optimization in management, and carefully considering cost-benefit analysis before implementing schedule compression techniques to effectively optimize construction projects.
- [2] Shashaa D. (2021) conducted research on, 'Analysis of effective optimization of construction technology in municipal engineering construction projects' Municipal engineering project building is becoming more challenging and complex, and it significantly affects urban people' quality of life. In addition to promoting sustainable growth and improving the national economy, construction technology optimization can have a favourable effect on the effectiveness and quality of construction. In conclusion, construction technique has a direct impact on the quality of municipal engineering construction projects. To strengthen market competitiveness, businesses should pay more attention to construction technology optimization and construction continuously improve technology management.
- [3] Ravande Kishor studied, 'Optimization of construction projects scheduling using primavera and genetic algorithm', The article highlights the value of managing resources in building projects and how genetic algorithms (GA) can be used as a global search method to address the scheduling issue associated with resource constraints. The study contrasts the outcomes from the GA technique utilizing Evolver software with those from the Primavera software, demonstrating that the GA strategy offers optimized results with a length of 317 days. For resource constrained project scheduling, the use of a genetic algorithm model has produced optimized results at lower prices.
- [4] The efficiency of the method was demonstrated by an actual project that was solved using this optimization software, which saw a 6.4 percent decrease in costs and a month's reduction in the overall project duration.

[5] Zolekar performed a study on 'Cost optimization of construction projects by using advance methods and advanced materials' conducted research on construction project cost optimization. They investigated cutting-edge techniques like prefabrication and Building Information Modelling (BIM), as well as the usage of cutting-edge materials. Their research intended to lower costs and boost construction's cost effectiveness. In conclusion, research concentrated on the cost optimization of construction projects through the employment of cutting-edge techniques and materials. Their research focused on life cycle costs while examining the advantages of BIM, prefabricated components, and novel materials.

3. OBJECTIVE OF THIS STUDY

- 1. Compare and contrast project management time & cost optimization techniques.
- 2. Give close attention to Lingo Solver's linear programming and Primavera P6.
- 3. Examine the advantages and disadvantages of each strategy.
- 4. Assess efficiency, precision, and flexibility in a range of project situations.
- 5. Offer decision-makers and project managers practical information.
- 6. Construct a bridge between sophisticated optimization tools and conventional software.
- 7. Add to a more complex comprehension of the usefulness and relevance of real-world application.

4. METHODOLOGY

- 1. **Review of Literature:** Performed a thorough analysis of the body of knowledge regarding cost optimization in project management, including studies on Primavera P6, linear programming, and the Lingo Solver. Wrote a summary of pertinent techniques and observations.
- 2. Choosing a Case Study: Chose a wide range of realworld project case studies that illustrate different project difficulties and industries which are appropriate for analysis using Lingo Solver for linear programming and Primavera P6.
- 3. **Gathering of Data:** Collected pertinent information for every case study that has been chosen, such as project schedules, resource allotments, financial restrictions, and actual expenses

SJIF Rating: 8.176

ISSN: 2582-3930

- 4. Creating Models for Linear Programming: Created the linear programming model using the gathered using LINGO solver and depicted situations for cost optimization, defining goal functions and restrictions.
 - 5. **Primavera P6 Analysis:** Use Primavera P6 to simulate project schedules and resource allocations for the chosen case studies. Recording of important information such as critical path, resource utilisation, and project completion times is done.
 - 6. **Performance Metrics:** Created a set of performance metrics, such as cost efficiency, resource utilisation, and schedule adherence, to evaluate both Primavera P6 and Linear Programming with Lingo Solver quantitatively.
 - 7. **Comparative Analysis:** Examined the results of the Primavera P6 simulations and Lingo Solver solutions for case study. Examined the advantages and disadvantages of each method in terms of cost optimization, resource utilisation, and schedule efficiency.
 - 8. **Results Synthesis:** Combine the quantitative and qualitative data to derive general conclusions about how well Primavera P6 and Linear Programming with Lingo Solver perform in comparison when it comes to project management cost optimization.

5. PROBLEM STATEMENT

In project management, achieving optimal cost outcomes is a constant difficulty. The purpose of this study is to compare the efficiency of two time & cost optimization approaches: Primavera P6 and Linear Programming using Lingo Solver. In order to help project managers select the best strategy for their projects, the purpose is to offer insight about their effectiveness, accuracy, and flexibility. The main query is: In a variety of project scenarios, which technique provides the best value in terms of both time and cost?

6. PROBLEM FORMULATION FOR LIVE VILLA CONSTRUCTION PROJECT

The project data presented below in fig. 01 & fig. 02 has been procured from the ongoing villa construction project through in-depth discussions with the Project Manager. The main goal is to crash the project's length compared to the original estimated completion time. The following data shows the activity and normal duration and cost required for each activity to be complete.

| ACTIVITIES | TASK NAME | DURATION | START | FINISH | COST | CRASH TIME | CRASH COST |

Fig -1.1: Live project data with annual cost

Initially as shown in Figure 3, a Gantt chart representing the project activities has been made in order to assist in developing of the Linear Programming Problem (LPP) model. In Gantt chart along the y axis, we can see the activities and on x axis, duration of each activity is represented.

Fig -1.2: Gantt chart of project activities

The project network diagram has then been created, to determine the Critical Path Length and Project Duration as well as the Earliest Start Time, Earliest Finish Time, Latest Start Time, and Latest Finish Time as represented in fig. no. 04.

7. PROJECT CRASHING USING LINEAR PROGRAMMING IN LINGO

As part of this methodological framework, we begin by meticulously developing a mathematical model that has been designed to handle every aspect of our project crashing condition. The main objective of this model, which is methodically constructed using Linear Programming techniques, is to minimize the overall cost of "crashing" or accelerating project activities. In order to provide an initial understanding, the project length is first approximated using network diagrams, like the Critical Path Method (CPM), or by using advanced project management software that accurately plots the duration of each action. For our particular scenario, this initial approximation provides a project duration that indicates the amount of time before any crashing operations.

The focus after that turns to defining critical decision variables that are essential to the optimization process. Here, we present 'X' as the variable that denotes the precise time at which a project event occurs. Particularly, this chronological measurement is made from the project's initiation or starting point, offering a comprehensive immediate framework for an in-depth analysis.

Therefore,

Y1 = time at which 1st event occurs

Y2 = time at which 2nd event occurs

Y 3 = time at which 3rd event occurs

Y4 = time at which 4th event occurs

Y5 = time at which 5th event occurs

Y6 = time at which 6th event occurs

Y7 = time at which 7th event occurs

Y8 = time at which 8th event occurs

Yn = No. of days activity n can be crashed.

In a similar manner, X1, X2, X3, X4, X5, X6, etc. represent for the number of days that can be crashed for Activities 2, 3, 4. 5, 6, 7, 8 etc., respectively

| ACTIVITY | ACTIVITY NAME | NORMAL | CRASH | NORMAL | CRASH | MAX CRASH | CRASH COST |

Fig -2.1

In the above figures no. 5 and 5.1, excel is used to determine the normal time, crash time, normal cost, and crash cost.

SJIF Rating: 8.176 ISSN: 2582-3930

As we can see in fig no. 03, the start time of every activity depends on the start time and duration of its immediate predecessors. Furthermore, as shown in Table 5 & 5.1, the crash cost per day, also known as the cost slope, has been calculated. We developed the following objective function using this cost slope and the decision variable X, which indicates the number of days an activity should be crashed:

Min(Z) = 4322x1 + 24597x2 + 7644x3+ 1557x4 + 23338x5+ 4575x6 + 5255x7 + 513x8 + 14438x9 + 2005x10 + 3622x11+ 4504x12+ 12134x13+ 9426x14+ 1925x15+ 1789x16+ 2986x17+ 2006x18+ 2004x19+ 2015x20+ 4030x21+ 23620x22

Z here is Objective function value which represents minimum crash cost & X represents the number of days each activity can be crashed i.e. for 22 activities.

The constraints are taken into consideration such as nonnegative constraints, crash time constraints, start time constraints & project completion constraints. Few are mentioned below:

Non negative constraint:

Crash time constraints:

| x1 | >= | 4 |
|-----|----------|-----|
| x2 | $\geq =$ | 1 |
| xЗ | <= | 2 |
| x4 | $\geq =$ | 2 |
| x5 | $\geq =$ | 5 |
| хб | $\geq =$ | 2 |
| x7 | $\geq =$ | 2 |
| x8 | $\geq =$ | 8 |
| x9 | $\geq =$ | 1 |
| x10 |) >= | = 5 |

Start time constraints:

y1 = 0 y2 + x2 >= 12 y3- x3+ y2 >= 20 y4- x4+ y3>= 10 y5- x5+ y4 >= 24 y6- x6+ y5>= 11 y7- x7+ y6>=45y8- x8+ y7>= 21 y9- x9+ y8>= 10 y10- x10+ y9>= 27

Project completion constraint:

Yfinish <= 501

And similarly for 22 activities.

7.2. PROCEDURE FOLLOWED IN LINGO

We construct a collection of variables to represent important project components in the first stage of using Lingo to optimize the project time. More specifically, we declare a variable called 'x' that represents the maximum number of days that an activity can crash. We also define a variable 'y' to indicate the time at which each event takes place, and 'y_finish integer' is used to indicate the time at which the project is finished.

We construct a collection of variables to represent important project components in the first stage of using Lingo to OPTIMIZE the project time. More specifically, we declare a variable called 'x' that represents the maximum number of days that an activity can crash. We also define a variable 'y' to indicate the time at which each event takes place, and 'y_finish integer' is used to indicate the time at which the project is finished.

Through systematic consideration of these factors, building the objective function, and implementation of suitable constraints, Lingo's optimization process is set up to produce a solution that minimizes project expenses and duration. Then, we go along and execute the model in our Lingo model after thoroughly outlining the variables, creating the objective function, and establishing the constraints. The process of optimization finalizes in the generation of results that provide significant understanding of the optimal approach to reduce project duration as well as associated costs.

Table -1: X and Y solution in LINGO

Fig -4: Time Distribution for each activity of Project

Our analysis has shown that, if the project is carried out in 530 days without using the crashing method, the total cost will be Rs 1,38,46,314. On the other hand, the project expenses increase to Rs. 1,41,50,256 if the crashing approach is used to meet the same 447-day completion deadline. The table below provides a summary of these findings' details.

| Project Duration | Direct Cost | The cost after Crashing | Total Cost |
|---------------------|-------------|-------------------------------|-------------|
| 501 days | 1,38,46,314 | - | 1,38,46,314 |
| 447 days | 1,38,46,314 | 3,03,942 | 1,41,50,256 |

Table -2: Total Cost Before and After Crashing.

8. PROCEDURE FOLLOWED IN PRIMAVERA P6

In order to achieve particular objectives, tasks must be arranged with specific start and finish points through project management. Project portfolios, which are controlled by an Enterprise Project Structure (EPS), allow for the viewing of data simultaneously. Critical responsibilities such as project, sales, and human resource managers are assigned under the Work Breakdown Structure (WBS). Project, Resource, and Global calendars are used by Primavera P6 to schedule resources and tasks, which is essential for efficient project management. The Work Breakdown Structure (WBS), which is especially important for multistory residential complexes, organizes project work. Activities are shown in a schedule chart that shows task durations and is handled by relationships (FS, SS, FF, SF). For effective task completion, resourcesincluding labor and machinery-are categorized according to unit costs and working hours. The Critical Path Methodology helps with scheduling, figuring out when a project should be finished, and identifying important paths.

8.1 RESULTS FOR PRIMAVERA P6

We discovered that the project will optimize cost was lower than its budgeted cost but only if we rescheduled and reallocated the resources and a new critical path and an optimized duration following the schedule crash.

| Sr. No. | Туре | cost |
|---------|---------------------|-----------------|
| 1. | Budgeted total cost | Rs. 1,38,46,314 |
| 2. | Optimized cost | Rs1,72,45,720 |

Table -3: Total Cost Before and After Crashing.

| Sr. No. | Туре | cost |
|---------|-------------------|----------|
| 1. | Original Duration | 501 Days |
| 2. | After Crashing | 486 Days |

Table -4: Total duration Before and After Crashing.

9. RESULTS AND CONCLUSION

According to the research findings, Lingo's use of linear programming (LP) significantly reduced the project's duration by 54 days, resulting in a cost of Rs. 1,41,50,256 for project activity disruption. It may be feasible to reduce the project duration even further, but doing so requires additional funds. Lingo has reduced project duration by 8.9%, a noteworthy figure considering that the cost was just Rs. 3,03,942.

Alternatively, with a total scheduling cost of Rs. 1,72,45,720, the project duration is shortened by 15 days when using Primavera P6. This results in a 2.3% reduced project duration, achieved with a 33,99,406 reduction in cost. Even though the cost of crashing increases up, the effect has been mitigated because, over the best part of the project's duration, the indirect costs are reduced as a result.

10. TECHNICAL COMPARISON BETWEEN LINGO AND PRIMAVERA P6

- A. Efficiency of Optimization:
- In comparison to Primavera P6, Lingo shows a greater percentage reduction in project length (8.9%).
- b. Primavera P6 reduces overall costs by a significant amount but at a lesser percentage (2.3%).

B. Benefit-Cost Analysis:

- a. Lingo spends comparatively less (Rs. 3,03,942) for a project that is completed much faster.
- b. While Primavera P6 delivers a relatively bigger overall cost reduction (Rs. 33,99,406), the reduction is not as significant.

C. Sensitivity to Costs of Crashing:

- **a.** Lingo exhibits sensitivity to cost crashing, where there is a more noticeable decrease in project duration.
- **b.** Primavera P6 shows a less noticeable decrease in project length, indicating a less responsive response to plummeting prices.

D. Trade-off Between Cost and Duration:

- a. Lingo provides better control over the optimization process by demonstrating a more distinct trade-off between project length and crashing expenses.
- b. Primavera P6 promotes flexibility in decision-making by striking a balance between cutting project time and lowering overall costs.

E. User-Friendliness:

- a. Users may face a longer learning curve as lingo may require a deeper comprehension of linear programming ideas.
- b. Primavera P6 is well-known for having a simple interface that allows planners and project managers to use it more widely.

F. Capabilities for Integration:

- a. It's possible that Lingo's integration capabilities with other project management software and tools are limited.
- b. Enhancing interoperability, Primavera P6 is frequently effortlessly connected with a variety of scheduling and project management applications.

G. Risk Reduction:

- a. Lingo's ability to precisely regulate project time and crashing costs makes it possible to implement careful risk management.
- **b.** Primavera P6 offers a more cautious approach to risk mitigation because of its emphasis on striking a balance between overall expenses and reduction.

In conclusion, the decision between Primavera P6 and Lingo is based on the planned trade-off between project duration and costs, user skills, and project-specific objectives. Primavera P6 is a potential solution for a wider user base due to its user-friendly interface and integration possibilities, even if Lingo may offer enhanced control over optimization conditions
