

A Review on PAPR Reduction Techniques for OFDM Systems

Sonam Chandel¹, Prof. Sanket Agrawal²

ABSTRACT: With increasing number of cellular network users, large data being generated and limited bandwidth available for efficient systems, multiplexing techniques are needed that use the available bandwidth efficiently for IoT Systems. One of the most efficient multiplexing techniques available presently is Orthogonal Frequency Division Multiplexing (OFDM). It is widely used in cellular and internet of things (IoT) based applications. One of the major challenges that OFDM suffers from is high value of Peak to Average Power Ratio (PAPR). This causes high Bit Error Rates and reduced Quality of Service. Hence it is necessary to reduce the PAPR of the OFDM systems. Several techniques have been employed so far for the reduction of PAPR in OFDM systems. This paper presents a review on the most common PAPR reduction techniques for OFDM systems.

Keywords: Cellular Networks, Orthogonal Frequency Division Multiplexing (OFDM), Peak to Average Power Ratio (PAPR), PAPR reduction.

I. INTRODUCTION

For any bandwidth constrained cellular system, the bandwidth would be limited, hence an effective multiplexing technique is needed. Thus, OFDM is widely chosen as the multiplexing technique for several applications such as cellular networks, IoT, Local Area Networks (LANs), WiMax etc. While transmitting the OFDM based IoT data, it is mandatory to ensure high reliability (Quality of Service) by reducing the BER value. However, this a severely challenging with fading condition and high power amplifiers need to be used to boost the OFDM signals. Hence, it is necessary to reduce the PAPR of the system to avoid the distortions in the finally received OFDM signal to maintain high reliability and Quality of Service.

Fig.1 Spectra of FDM and OFDM

Figure 1 shows the spectra of OFDM and FDM (frequency division multiplexing). It can be seen that OFDM helps to save critically important bandwidth. Use of OFDM has 2 benefits:

- 1. The saved bandwidth can be used to accommodate more users
- 2. The saved bandwidth can be distributed among users to provide them with more bandwidth.
- 3. Higher bandwidth per user means high speed of data transfer.

II. PEAK TO AVERAGE POWER RATIO.

The peak to average power ratio (PAPR) of the system is defined as the ratio of the peak power to that of the average power of the system

Mathematically, it is defined as:

$$PAPR = \frac{\max{\{X(t)^2\}}}{mean{\{X(t)^2\}}}$$
(1)

Here,

PAPR stands for peak to average power ratio X(t) is the transmitted signal

I

Max represents the peak of the signal

Mean represents the average value

The significance of this term lies in the fact that the PAPR gives the deviation of the signal from the average power thereby making higher distortions in High Power Amplifiers (HPAs). OFDM inherently suffers from high PAPR which results in increased errors at the receiving end of networks. Thus it is necessary to reduce the PAPR of the system.

Figure 2 shows the graphical representation of PAPR of the system where the peak power greatly exceeds the average power.

III. RELATED WORK

This section presents the major noteworthy contribution in the domain of research on PAPR reduction in OFDM systems in tabular form.

IV. CCDF FOR PAPR ANALYSIS

The Peak to Average Power Ratio (PAPR) can be analyzed using a probability function called the Complementary Cumulative Distribution Function or CCDF. Mathematically CCDF for PAPR can be defined as:

$$y = Prob \left(PAPR > PAPR_0 \right) \quad (2)$$

The CCDF of the PAPR denotes the probability that the PAPR of a data block exceeds a given threshold $PAPR_0$.

Fig.3 Typical PAPR CCDF graph for OFDM systems Figure 3 shows a typical CCDF graph for the PAPR analysis. The graphs shows that as the value of PAPR increases, the chances or probability that the system PAPR would exceed the threshold PAPR reduces. A quick drop in the CCDF graph for low values of PAPR is desirable.

V. CONCLUSION

It can observed that cellular and IoT applications are bandwidth constrained. OFDM is one of the most effective multiplexing techniques for cellular systems but suffers from the problem of high PAPR. It is necessary to reduce PAPR and also ensure no or very data loss. This paper presents a review on the fundamentals of OFDM along with the problem of PAPR. The various PAPR reduction techniques used in contemporary work have also been cited.
