## Sentiment Analysis of Social Media Tweets Through Probabilistic Neural Classifier

Archana Parihar<sup>1</sup>, Prof. Pankaj Raghuwanshi<sup>2</sup>

Abstract— Of late, big data and big data analytics has fund applications in diverse fields. Social media and allied applications is one such domain for research, where Artificial Intelligence has shown unprecedented impact. In this paper a mechanism has been proposed which can classify text data into classes of different sentiments. Data in the form of tweets has been used in this case. Pre-processing of raw data has been done prior to using it to train a neural network. A Neural Network is then trained using the categories of the data which are tweets that correspond to happy, neutral and sad moods of the Twitter users. The Bayesian Regularization (BR) algorithm has been used for training the artificial neural network. It has been observed that this proposed technique achieves an accuracy of 96.90% which is significantly lesser compared to previously existing work.

Keywords—Artificial Neural Network (ANN), Text Mining, Bayesian Regularization, Mean Square Error (MSE).

#### I. INTRODUCTION

The advent of data analytics has been enormous and text mining and opinion mining has garnered huge importance because of its broad range of applications in a variety of domains like the social media, analytics of data, business applications etc. Sentiment analysis can be defined as a study that is based on a computational analysis and determination of textual opinions, emotions, behaviour and the attitude exhibited towards any entity. [5] Sentiment analysis tries to find out the attitude or an opinion of the user based user's textual data. It also aids in making decisions. Sentiment Analysis helps in determining whether the piece of tweet or any piece of writing is positive, negative or neutral. It analyses the sentiment behind the text of any

user, hence it helps companies for product reviews and enhance business prospects. It has got a broad range of applications today, especially in the areas where outcomes are dependent on human sentiments and opinions. It can also be considered as opinion mining. To be able to analyse and implement such tasks, Artificial Intelligence is used. In this context, the concept of data mining is utilized which a knowledge based procedure which is based on extraction of skilled patterns and information. The extracted data is then used in visualization of applications and creation of real time programs for the process of decision making. The applications can be diverse such as marketing and finance, advertising, opinion polls, social media, product reviews just to name a few. The following diagram illustrates the mechanism.

ISSN: 2582-3930

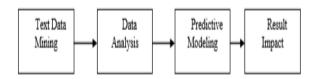

Fig.1 Text Mining model for sentiment analysis

While several data sources are available on the internet to be mined, yet a judicious use of web mining is to be done prior to any system design model is to be used. The critical factor is also the feature selection from the raw data to be included in the analysis of the data as a whole. The unstructured text mining approach is often used and the text is to be replaced with suitable tokens or numerical counterparts prior to training any designed mechanism for the classification of the text data [3]. While data as a whole can consist of more than textual data, hence pre-processing of the data is of topmost The automated classification of sentiment priority. based classification can be leveraged in several applications which need an automated mechanism for

sentiment classification. The major challenge in this section is the proper training of the automated system as the training accuracy would yield high classification accuracy later [4].

# II. CONTEXTUAL ANALYSIS AND DEEP LEARNING

One of the major challenges in sentiment analysis is the contextual analysis of data. The different aspects are discussed subsequently [5].

### 2.1 Contextual Analysis

It is often difficult to estimate the context in which the statements are made. Words in textual data such as tweets can be used in different contexts leading to completely divergent meanings.

### 2.2 Frequency Analysis

Often words in textual data (for example tweets) are repeated such as

##I feel so so so happy today!!

In this case, the repetition of the word is used to emphasize upon the importance of the word. In other words, it increases to its weight. However, such rules are not explicit and do not follow any regular mathematical formulation because of which it is often difficult to get to the actuality of the tweet [6].

# 2.3 Converting textual data into numerically weighted data

The biggest challenge in using an ANN based classifier is the fact that the any ANN structure with a training algorithm doesn't work upon textual data directly to find some pattern. It needs to be fed with numerical substitutes [7]. Hence it becomes mandatory to replace the textual information with numerical information so as to facilitate the learning process of the neural network [8]

the machine or artificial intelligence system requires training for the given categories [9]. Subsequently, the neural network model needs to act as an effective classifier. The major challenges here the fact that sentiment relevant data vary significantly in their parameter values due to the fact that the parameters for each building is different and hence it becomes extremely difficult for the designed neural network to find a relation among such highly fluctuating parameters. Generally, the Artificial Neural Networks

model's accuracy depends on the training phase to solve new problems, since the Artificial Neural Networks is an information processing paradigm that learns from its environment to adjust its weights through an iterative process [10].

Deep learning models do have the capability to extract meaning form large and verbose datasets by finding patterns between the inputs and targets. Since neural nets directly process numeric data sets, the processing of data is done prior to training a neural network [11]. The texts are first split into training and testing data samples in the ratio of 70:30 for training and testing. Further, a data vector containing known and commonly repeated spam and ham words is prepared [12]. Text normalization is followed by removal of special characters and punctuation marks.

Subsequently the data set structuring and preparation is performed based on the feature selection. The deep learning structure is depicted in figure 2 [13].

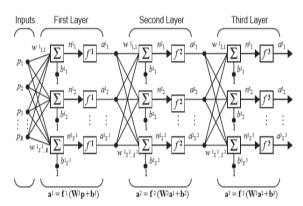

Fig.2 The deep learning structure

The deep learning structure is depicted in figure 2 and it is basically a cascade of stacked neural networks [14]. Multiple hidden layers facilitate the analysis of complex data. The cascading weight updating can be understood as [15]:

$$a^n = \varphi_n(\varphi_{n-1} \dots \varphi_1\{wp + b\}) \qquad (1)$$

Here,
W is the weight
b is the bias
a is the input to the final nth layer
φ is the activation function

#### III. PROPOSED ALGORITHM

The proposed approach is mathematically modelled as:

The prepared data vector for training is used for training wherein the weights are initialized randomly. A stepwise implementation is done as [16]:

1. Prepare two arrays, one is input and hidden unit and the second is output unit.

Here, a two dimensional array  $W_{ij}$  is used as the weigt updating vector and output is a one dimensional array  $Y_{i}$ .

3. Original weights are random values put inside the arrays after that the output.

$$x_i = \sum_{i=0} y_i W_{ij} \tag{2}$$

Where.

 $y_i$  is the activity level of the  $j^{\text{th}}$  unit in the previous layer and

 $W_{ij}$  is the weightof the connection between the i<sup>th</sup> and the j<sup>th</sup> unit.

4. Next, activation is invoked by the sigmoid function applied to the total weighted input.

$$y_i = \left[\frac{e^x - e^{-x}}{e^x + e^{-x}}\right] \tag{3}$$

Summing all the output units have been determined, the network calculates the error (E).

$$E = \frac{1}{2} \sum_{i} (y_i - d_i)^2$$
 (4)

Where,  $y_i$  is the event level of the  $j^{th}$  unit in the top layer and  $d_i$  is the preferred output of the  $j_i$  unit [17].

### A. Implementing Back Prop:

Calculation of error for the back propagation algorithm is as follows:

Error Derivative  $(EA_j)$  is the modification among the real and desired target:

$$EA_j = \frac{\partial E}{\partial y_j} = y_j - d_j \tag{5}$$

Here,

E represents the error

y represents the Target vector

d represents the predicted output

Error Variations is total input received by an output changed given by:

ISSN: 2582-3930

$$EI_{j} = \frac{\partial E}{\partial X_{i}} = \frac{\partial E}{\partial y_{i}} X \frac{dy_{j}}{dx_{i}} = EA_{j} y_{j} (1 - y_{i})$$
 (6)

Here,

E is the error vector

X is the input vector for training the neural network In Error Fluctuations calculation connection into output unit is computed as:

$$EW_{ij} = \frac{\partial E}{\partial W_{ii}} = \frac{\partial E}{\partial X_i} = \frac{\partial X_j}{\partial W_{ii}} = EI_j y_i \qquad (7)$$

Here,

W represents the weights

I represents the Identity matrix

I and j represent the two dimensional weight vector indices

Overall Influence of the error:

$$EA_{i} = \frac{\partial E}{\partial y_{i}} = \sum_{j} \frac{\partial E}{\partial x_{j}} X \frac{\partial x_{j}}{\partial y_{i}} = \sum_{j} EI_{j} W_{ij} \quad (8)$$

The partial derivative of the Error with respect to the weight represents the error swing for the system while training. The gradient is computed as:

$$g = \frac{\partial e}{\partial w} \tag{9}$$

Here,

g represents the gradient

e represents the error of each iteration

w represents the weights.

The gradient is considered as the objective function to be reduced in each iteration. A probabilistic classification using the Bayes theorem of conditional probability is given by:

$$P\left(\frac{H}{X}\right) = \frac{P\left(\frac{X}{H}\right)P(H)}{P(X)} \tag{10}$$

Here

Posterior Probability  $[P\ (H/X)]$  is the probability of occurrence of event H when X has already occurred Prior Probability  $[P\ (H)]$  is the individual probability of event H

Page 3

SJIF RATING: 8.448

X is termed as the tuple and H is is termed as the hypothesis.

Here, [P (H/X)] denotes the probability of occurrence of event X when H has already occurred.

The final classification accuracy is computed as:

$$Ac = \frac{TP + TN}{TP + TN + FP + FN} \tag{11}$$

Here.

**TP** represents true positive

**TN** represents true negative

**FP** represents false positive

**FN** represents false negative

#### IV. RESULTS

The proposed system utilizes the textual data in the form of tweets to be analyzed based on positive, negative and neutral tokens to be represented by -1, 0 and 1 respectively. Subsequently, the number of tokens with

polarity is also fed to the neural network as a training parameter.

Table 1. Summary of Results

Parameter	Value
ML category	Deep Supervised Learning
No. of hidden	5
layers	
Iterations	18
Error	3.10
Accuracy	96.90
(Proposed Work)	
Accuracy	93.5%
(Previous Work)	

### **CONCLUSION**

Sentiment analysis has a wide range of applications in information systems, including classifying reviews, summarizing review and other real time applications. There are promising possibilities to use sentiment analysis in real time business models. The present work focuses on sentient analysis by classification of tweets from social media (twitter) data. In this case, a deep Bayes net has been employed for training and subsequent testing of tweets. The Bayesian Regularization (BR) algorithm has been used and their respective results show variation in outcomes because of its probabilistic classification. It has been shown that the proposed algorithm attains a classification accuracy of 96.90% which is substantially higher than previously existing method.
